Preface

The University of Waterloo Software Engineering (SE) SE350 course laboratory project is to design a small real-time executive (RTX) and implement it on a Keil MCB1700 board populated with an NXP LPC1768 microcontroller.

The main purpose of this document is a quick reference guide of the relevant hardware environment and software development tools of the Keil MCB1700 board for completing the laboratory project. To make the manual self-contained, we also include the project description ¹ to further guide students.

There are three parts of the document.

- Part I: Lab Project Administration Policy
- Part II: RTX Project Description
- Part III: Design and Implementation Notes
- Part IV: Keil MCB1700 Reference Guide

Acknowledgments

We would like to sincerely thank Professor Paul Dasiewicz who originally designed the RTX course project and provided us with detailed notes and sample code. We also own many thanks to our students who did this course project in the past and provided constructive feedback. Professor Sebastian Fischmeister made the Keil Boards and MDK-ARM donations possible. Professor Jim Barby provided timely departmental resource towards the development of the course project, without which this project will not be possible to start. Roger Sanderson provided us with all necessary experiment tools and resources, which we

¹The original project description was written by Professor Paul Dasiewicz. The project description included in this manual is a modified version of the original one.

are grateful for. We appreciate that Bernie Roehl has shared his valuable Keil board experiences with us. Our gratitude also goes out to Eric Praetzel who sets up the RTOS lab and also maintains the Keil software on Nexus machines; Laura Winger who managed to customize the boards so that we have the neat plastic cover to protect our hardware. Bob Boy from ARM always answers our questions in a detailed and timely manner. Rollen S. D'Souza shared his recent lab teaching experiences with us and this helped us to improve the manual. Thank everyone who has helped.

Part I

Lab Project Policy

Lab Project Administration Policy

Project Group Policy

- **Group Size.** The project is done in groups of four. A group of less than four members is not recommended. There is no reduction in project deliverables regardless the size of the project group. Everyone in the group normally gets the same mark. The Learn system (<https://learn.uwaterloo.ca>) is used to signup for groups. *The project group signup is due by 4:30pm on the second Friday of the academic term.* Late group sign-up incurs a **5%** per day final lab mark deduction.
- **Group Split-up.** If you notice workload imbalance, try to solve it as soon as possible within your group or split-up the group as the last resort. Group split-up is only allowed once. There is *one grace day deduction penalty* to be applied to each member in the old group. We highly recommend everyone to stay with your group members as much as possible, for the ability to do team work will be an important skill in your future career. Please choose your lab partners carefully and wisely. A copy of the code and documentation completed before the group split-up will be given to each individual in the group.
- **Group Split-up Deadline.** To split from your group for a particular project deliverable, you need to notify the lab instructor in writing and sign the group split-up form in the appendix at least one week before the particular project deliverable is due.

Project Submission Policy.

- **Project Deliverables.** The project is divided into four deliverables. Each deliverable includes the source code and a documentation file (in pdf file) ². Archive all files for each deliverable in a single file and submit it by using the corresponding Learn dropbox. Table 1 gives the weight, deadline and naming convention of each deliverable. We also give the class an option to combine P2 and P3 deliverables into one single deliverable and takes the P3 deadline in this case. Groups who choose to combine P2 and P3 into one deliverable need to notify the lab instructor and teaching assistants in writing through email by *16:30 Mar. 13th*. Make sure you include your Group ID in your email subject line.

²Put all source code (including all header files and binaries) and the documentation file in a separate directory. Include a README file with group identification, description of directory contents. Compress the directory contents into a single file. For archiving, you must choose zip.

Deliverable	Weight	Due Date	File Name
Group Sign-up		16:30 Jan 17	
RTX P1	30%	08:30 Feb 03	p1_Gid.zip
RTX P2	30%	08:30 Mar 16	p2_Gid.zip
RTX P3	15%	08:30 Mar 30	p3_Gid.zip
RTX P4	25%	23:59 Apr 03	p4_Gid.zip

Table 1: Project Deliverable Weight and Deadlines. Replace the “id” in “Gid” with the two digit group ID

Submissions will be evaluated on the board in lab. A 15% penalty will be applied to a deliverable that is only able to function inside the simulator but not on the actual hardware.

- **Late Submissions.** There are *three grace days*³ that can be used for project deliverables late submissions without incurring any penalty. A group split-up will consume one grace day. When you use up all your grace days, a 10% per day late penalty will be applied to a late submission. *Submission is not accepted if it is more than three days late.* Please be advised that to simplify the book-keeping, late submission is counted in a unit of day rather than hour or minute. An hour late submission is one day late, so does a fifteen hour late submission. Unless notified otherwise, we always take the latest submission from the Learn dropbox.

Seeking Help Outside Scheduled Lab Hours

- **Discussion Forum.** We recommend students to use the Piazza (<https://piazza.com/uwaterloo.ca/winter2020/se350/>) to ask the teaching team questions instead of sending individual emails to lab teaching staff. For a question related to a particular deliverable, our target response time is one business day before the deadline of the particular deliverable⁴. *After the deadline, there is no guarantee on the response time.*
- **Office Hours.** During weeks where there are no scheduled labs, lab teaching staff hold bi-weekly office hours. Check the LAB calendar posted on Piazza (<https://piazza.com/uwaterloo.ca/winter2020/se350/>) for office hour details.

³Grace days are calendar days. Days in weekends are counted.

⁴Our past experiences show that the number of questions spike when deadline is close. The teaching staff will not be able to guarantee one business day response time when workload is above average, though we always try our best to provide timely response.

- **Appointments.** Students can also make appointments with lab teaching staff should their problems are not resolved by discussion forum or during office hours. When you request an appointment, please specify three preferred times and roughly how long you would like the appointment to be. On average, an appointment is fifteen minutes per project group. Please also summarize the main questions to be discussed in your appointment requesting email.

Please note teaching staff are not permitted to give direct solution to lab project. Guidance and hints will be provided to help students to find solutions by themselves. This applies to debugging as well. Note that debugging is a non-trivial part of the work of the lab project. Teaching staff will not debug student's program for the student to complete the lab. Teaching staff will be able to demonstrate how to use the debugger and provide case specific debugging tips to help students better debug their programs.

Lab Facility After Hour Access Policy

After hour access to the lab will be given to the class when we start to use the Keil boards in lab. However please be advised that the after hour access is a privilege. Students are required to keep the lab equipment and furniture in good conditions to maintain this privilege.

No food or drink is allowed in the lab. Please be informed that you may share the lab with other classes. When resources become too tight, certain cooperation is required such as taking turns to use the stations in the lab.

Part II

RTX Project Description

Chapter 1

Introduction

1.1 Overview

In this project, you will design a small real-time executive (RTX) and implement it on a Keil MCB1700 board populated with an NXP LPC1768 microcontroller . The executive will provide a basic multiprogramming environment, with five priority levels, preemption, simple memory management, message-based inter-process communication, a basic timing service, system console I/O and debugging support.

Such an RTX is suitable for embedded computers which operate in real time. A co-operative, non-malicious software environment is assumed. The design of the RTX should allow its placement in ROM. Applications and non-kernel RTX processes must execute in the unprivileged level of LPC1768. The RTX kernel will execute in the privileged level ¹. It has 32K of RAM for use by the RTX and application processes. It contains four timers, four UARTs and several other peripheral interface devices. The board has two RS-232 interfaces, from which UART0 is used for your RTX system console and UART1 is used for your RTX debug terminal.

1.2 Summary of RTX Requirements

The summary of the RTX requirements are listed as follows:

¹We do not require application processes to use Process Stack Pointer (PSP). You may use the Main Stack Pointer (MSP) both for your kernel and non-kernel code. However non-trivial implementations that are not required such as using PSP for user processes and using memory protection unit to safe guard kernel sensitive data will be rewarded with bonus marks.

1. Scheduling Strategy

Four user priority levels plus an additional “hidden” priority level for the Null process, preemption, no time slicing, FIFO (First In, First Out) discipline at each priority level.

2. RTX Primitives and Services

Refer to the Chapter 2 (Description of RTX Primitives and Services).

3. RTX Footprint and Processor Loading

A reasonably *lean* implementation is expected. No standard C library function call is allowed in the kernel code.

4. Error Detection and Recovery

At minimum, the RTX kernel must detect one type of error: an attempt to `send_message` to or `set_process_priority` of a non-existent process ID. The primitive will return an error code (a non-zero integer value). No error recovery is required. It may be assumed that the application processes can deal with this situation.

Chapter 2

Description of RTX Primitives and Services

This chapter lists the RTX primitive and services. You must implement these as described and may not modify the prototypes in any way. The primitives listed below will always return a value, either a pointer or an `int` return code. In the latter case, the return code value of 0 indicates a success; non-zero value indicates a failure where applicable.

2.1 Memory Management

The RTX supports a simple memory management scheme. The memory is divided into blocks of fixed size (128 bytes minimum). The size and the number of these blocks is a configuration parameter at compile time ¹. The blocks can be used by the requesting processes for storing local variables or as envelopes for messages sent to other processes. A block which is no longer needed must be returned to the RTX. Two primitives are to be provided.

```
void *request_memory_block();
```

The primitive returns a pointer to a memory block to the calling process. If no memory block is available, the calling process is blocked until a memory block becomes available. If several processes are waiting for a memory block and a block becomes available, the highest priority waiting process will get it.

¹For example, you may define a macro as the number of memory blocks and change the macro value at compile time.

```
int release_memory_block(void *memory_block);
```

This primitive returns the memory block to the RTX. If there are processes waiting for a block, the block is given to the highest priority process, which is then unblocked. The caller of this primitive never blocks, but could be preempted. Thus, it may affect the currently executing process.

2.2 Processor Management

One primitive is to be provided.

```
int release_processor();
```

This primitive transfers the control to the RTX (the calling process voluntarily releases the processor). The invoking process remains ready to execute and is put at the end of the ready queue of the same priority. Another process may possibly be selected for execution.

2.3 Process Priority

Process priorities have an integer priority value (0, 1, 2, 3, 4) where 0 is the highest priority level. Two primitives are to be provided to set and get the process priority.

```
int set_process_priority(int process_id, int priority);
```

This primitive sets the priority of the process with **process_id** to the value given in **priority**. A process may change priority of any process (including itself) except for i-processes (see Section 3.2). The priority of the null process may not be changed from level 4 and it is the only process that can be assigned to level 4 (see Section 3.1.1). The caller of this primitive never blocks, but could be preempted. The preemption may affect the currently executing process.

```
int get_process_priority(int process_id);
```

This primitive returns the priority of the process specified by the **process_id** parameter. For an invalid **process_id**, the primitive returns -1.

2.4 Interprocess Communication

The RTX will support a message-based Interprocess Communication (IPC) discussed in lectures. Messages are carried in envelopes (memory blocks, see below) with a header which is less than 64 bytes. Two IPC primitives will be implemented.

```
int send_message(int process_id, void *message_envelope);
```

This primitive delivers to the destination process identified by `process_id` a message carried in a message envelope. The `message_envelope` argument is a pointer to the following general form structure:

```
struct msgbuf {  
#ifdef K_MSG_ENV  
    void *mp_next;    /* ptr to the next message */  
    int m_send_pid;    /* sender pid */  
    int m_recv_pid;    /* receiver pid */  
    int m_kdata[5];    /* extra 20B kernel data place holder */  
#endif  
    int mtype;        /* user defined message type */  
    char mtext[1];    /* body of the message */  
};
```

The fields that are enclosed in the `#ifdef K_MSG_ENV` and `#endif` form a data structure that kernel uses to manage the message passing. If the `K_MSG_ENV` is defined, then these fields will be exposed to user space. The user processes however should not access these fields even they are exposed to the user space. The kernel are responsible for modifying these fields. If the `K_MSG_ENV` is not defined, then the afore mentioned kernel fields will be hidden from the user space and the kernel is responsible to find space to store these fields.

User processes are permitted to read and write the `mtype` and `mtext` fields. The `mtype` field takes a user defined message type. And the following macro defines the value of this field:

DEFAULT

A general purpose message.

KCD_REG

A message to register a command with the Keyboard Command Decoder Process (see Section 3.1.2)

KCD_CMD

A message that contains a command.

CRT_DISPLAY

A message to display the message body to the RTX console.

These macros are defined in `common.h`, which is included by `rtx.h` file as follows.

```
#define DEFAULT 0
#define KCD_REG 1
#define KCD_CMD 2
#define CRT_DISPLAY 3
```

You are free to add more user defined message type macros.

The `mtext` field is an array (or other structure) whose size is limited to the size of one memory block less the total size of all other fields in the `msgbuf` structure. The primitive changes the state of destination process to ready-to-execute if appropriate. The sending process is preempted if the receiving process was blocked waiting for a message and has higher priority, otherwise the sender continues executing.

```
void *receive_message(int *sender_id);
```

This is a blocking receive. If there is a message waiting, a pointer to the message envelope containing it will be returned to the caller. If there is no such message, the calling process blocks and another process is selected for execution. The sender of the message is identified through `sender_id`, unless it is NULL. Note the `sender_id` is an output parameter and is not meant to filter which message to receive.

2.5 Timing Services

Unprivileged level processes obtain the timing service from RTX by the following primitive².

```
int delayed_send(int process_id, void *message_envelope, int delay);
```

The invoking process does not block. The message (in the memory block pointed to by the second parameter) will be sent to the destination process (`process_id`) after the expiration of the delay (timeout, given in *millisecond* units).

²Unprivileged processes should not read kernel timer data directly. You are free to add a primitive to return the kernel clock ticks to unprivileged processes should you find the `delayed_send` primitive is not sufficient to provide the timing service you need.

Chapter 3

Required Processes

This chapter describes the processes which you must implement for the project. The initial priority of processes is in the range of $\{0, 1, 2, 3\}$ and is left as a free choice if it is not specified explicitly. Note the I-processes (see Section 3.2) are not scheduled based on the priority. They are triggered by interrupts hence has no initial priority.

3.1 System Processes

System processes are those processes needed by the system to perform basic services (scheduling and I/O). You will need to make your design choice to determine which system processes require privileged level and which system processes may operate at unprivileged level.

3.1.1 The Null Process

This process runs as the lowest priority process (level 4) in the RTX. The Null process is the only process assigned to level 4. Level 4 is basically a “hidden” priority level reserved for the Null process. This preserves the four levels of user priorities (levels 0, 1, 2 and 3). Process id 0 is reserved for the null process. Initially, the following pseudo code can be used to design your null process:

```
loop forever
    release the processor
end loop
```

Once you have preemption working, then the “**release the processor**” line could be removed from the infinite loop.

3.1.2 System Console I/O Processes

The system console is used for communication with the RTX and application processes. It consists of two devices: keyboard and CRT display. These two devices communicate serially with the microcomputer; using the receive and transmit lines of one of the two RS-232 ports.

The RTX will include two system processes, the Keyboard Command Decoder (KCD) process and the CRT Display process. These processes work in cooperation with the UART interrupt handler i-process.

The Keyboard Command Decoder (KCD) Process

A keyboard command starts with the prompt character %, followed by a single (or multiple) letter command identifier and possibly additional command data. For example, %WS 12:45:00 could be a command to the wall clock process, telling it to start the wall clock display and setting the current time to 12:45:00 (where the command format is %WS hh:mm:ss). The W is a single command identifier and the S 12:45:00 following W are additional command data.

The command decoder process responds to two types of messages: command registration and console keyboard input. The former contains the command identifier and the process id of the process to which such commands are to be delivered when entered on the console keyboard. The processing of messages received depends on their type:

- Command Registration

The command identifier is associated with the process id of the registrant. To register a command with KCD, a process will send a message with type of KCD_REG and the body of the message starts with % followed by the command identifier (for example W for wall clock related commands) and a null character to terminate the message (See Q3 in Section 6.3 for a more detailed example).

- Keyboard Input

The string input is sent to CRT display for output. If the string begins with a registered command identifier, it is also sent to the registered requester.

The CRT Display Process

This process responds to only one message type: a CRT display request. The message body contains the character string to be displayed. The string may contain control characters (e.g. newline). The process causes the string to be output to the console CRT. In printing to the console display, the process must use the UART i-process. Any message received is freed using the `release_memory_block` primitive.

3.2 Interrupt Processes (I-Processes)

Two interrupt handling processes are required:

3.2.1 The Timer I-Process

The timer i-process is executed each time a hardware timer interrupt occurs. The timer i-process should handle the delivery of delayed send messages after the required time has expired.

3.2.2 The UART I-Process

The UART i-process uses interrupts for both the transmission and receiving of characters from the serial port. No polling or busy waiting strategies may be implemented. The UART i-process forwards characters (or commands) received to the KCD, and also responds to messages received from the CRT display process to transmit characters to the serial port.

Three Hot Keys

As well, the UART i-process is used to provide debugging services which will be used during the demonstration. Upon receiving a specific character (a hot key - your choice, e.g., !) as input, the UART i-process will print one of the following to the RTX system debug terminal.

- The processes currently on the ready queue(s) and their priority.
- The processes currently on the blocked on memory queue(s) and their priorities.
- The processes currently on the blocked on receive queue(s) and their priorities.

As well, you are free to implement other hot keys to help in debugging. For example, a hot key which lists the processes, their priorities, their states; or another which prints out the number of memory blocks available. Like all other debug prints, the hot key implementation should be wrapped in

```
#ifdef _DEBUG_HOTKEYS
...
#endif
```

preprocessor statements and should be turned off during automated testing. If the automated test processes fail, you may be asked to turn the hot keys on again in determining why the test processes are failing. Another hot key debug printout may be used to display recent interprocess message passing. A (circular) log buffer keeps track of the 10 most recent `send_message` and `receive_message` invocations made by the processes; upon receiving a specific hot key, these most recent 10 sent and 10 received messages are printed to the debug con-sole. The number 10 is used only as an example. The information printed could contain information such as:

- Sender process id
- Destination process id
- Message type
- First 16 bytes of the message text
- The time stamp of the transaction (using the RTX clock)

3.3 User Processes

These processes operate at *unprivileged level* and will be used to demonstrate the operation of your system.

3.3.1 User-Level Test Process

Write up to six user-level test processes to test your own OS. These test processes should run at unprivileged level and do not assume any kernel level data structures. These test processes only call the RTX APIs. The test processes should provide at least two and at

most six test cases and finish testing within three minutes. The process id 1, 2, 3, 4, 5, and 6 are reserved for these processes.

Since the test processes have no knowledge of your detailed internal design, they only invoke the functions specified by the RTX API. The test processes can use the timer that is not used by the RTX for timing testing. We require the testing results to follow the following format and you output the results to the putty terminal (i.e. UART0):

```
Gid_test: START
Gid_test: test n OK
Gid_test: test m FAIL
Gid_test: x/N tests OK
Gid_test: y/N tests FAIL
Gid_test: END
```

For example, if you are group G099 and you have 3 testing cases in total. Two of the testing cases pass and one of the testing cases does not pass. The final testing results should be output to putty terminal as follows:

```
G099_test: START
G099_test: total 3 tests
G099_test: test 1 OK
G099_test: test 2 OK
G099_test: test 3 FAIL
G099_test: 2/3 tests OK
G099_test: 1/3 tests FAIL
G099_test: END
```

3.3.2 24 Hour Wall Clock Display Process

This process registers itself with the Keyboard Command Decoder process as the handler for the %W command.

- The %WR command will reset the current wall clock time to 00:00:00, starts the clock running and causes display of the current wall clock time on the console CRT. The display will be updated every second.
- The %WS hh:mm:ss command sets the current wall clock time to hh:mm:ss, starts the clock running and causes display of the current wall clock time on the console CRT. The display will be updated every sec-ond.
- The %WT command will cause the wall clock display to be terminated.

3.3.3 Set Priority Command Process

This process registers itself with the Keyboard Command Decoder process as the handler for the %C command. The %C command has two parameters: %C `process_id` `new_priority` where `process_id` and `new_priority` are integers. This command changes the priority of the specified process, `process_id`, to `new_priority`. The change in priority level is immediate. It could also affect the target process's position on a ready queue or a blocked resource queue. The parameters must be verified to ensure a valid `process_id` and priority level is given. A %C command with illegal parameters will be ignored with an error message printed on the console.

3.3.4 Stress Test Processes

An important category of software tests are the stress tests. These tests seek to verify the behaviour of the system under heavy stress scenarios. One such scenario is depletion (or near depletion) of system resources. For the demonstration of this project, you will implement three processes whose behaviour is described below. The stress scenario being tested is depletion of memory blocks.

Process A:

```
p <- request_memory_block
register with Command Decoder as handler of %Z commands
loop forever
  p <- receive a message
  if the message(p) contains the %Z command then
    release_memory_block(p)
    exit the loop
  else
    release_memory_block(p)
  endif
endloop
num = 0
loop forever
  p <- request memory block to be used as a message envelope
  set message_type field of p to count_report
  set msg_data[0] field of p to num
  send the message(p) to process B
  num = num + 1
  release_processor()
endloop
```

```
// note that Process A does not de-allocate
// any received envelopes in the second loop
```

Process B:

```
loop forever
  receive a message
  send the message to process C
endloop
```

Process C:

```
perform any needed initialization and create a local message queue
loop forever
  if (local message queue is empty) then
    p <- receive a message
  else
    p <- dequeue the first message from the local message queue
  endif

  if msg_type of p == count_report then
    if msg_data[0] of p is evenly divisible by 20 then
      send "Process C" to CRT display using msg envelope p
      hibernate for 10 sec
    endif
  endif
  deallocate message envelope p
  release_processor()
endloop
```

The line “hibernate for 10 sec” is further expanded as:

```
q <- request_memory_block()
request a delayed_send for 10 sec delay with msg_type=wakeup10 using q
loop forever
  p <- receive a message //block and let other processes execute
  if (message_type of p == wakeup10) then
    exit this loop
  else
```

```

    put message (p) on the local message queue for later processing
  endif
endloop

```

Notes:

- Process C has a local message queue (distinct from the incoming message queue maintained by the RTX) onto which it enqueues (in FIFO order) messages which arrive while it hibernates. It processes these messages later.
- For your own testing, set the priority levels for processes A, B and C to values which are most likely to cause memory block depletion in the RTX. During project demo, you may be asked to re-initialize your RTX with TA/instructor specified priorities for A, B, and C and vary the total number of message envelopes available.

3.4 Process ID Assignment

To facilitate the project evaluation, we enforce the process ID assignment rule listed in Table 3.1.

process ID	Process	Process ID	Process
0	Null	8	B
1	Test 1	9	C
2	Test 2	10	Set process priority process
3	Test 3	11	Wall clock display
4	Test 4	12	KCD
5	Test 5	13	CRT
6	Test 6	14	Timer i-process
7	A	15	UART i-process

Table 3.1: Required RTX Processes

Chapter 4

RTX Initialization

To make the RTX more generally applicable, the RTX will be configured at initialization as specified in the RTX Configuration Table. This table has three sections:

1. Memory configuration section: memory block size, number of memory blocks created;
2. System process section;
3. Application process section.

Chapter 3 (Required Processes) lists the processes to be created. Each entry contains the following data:

- process id,
- priority,
- stack size,
- start address, and
- for system processes, whether the process is an i-process.

All initializations must take place after the RTX execution starts.

Chapter 5

Deliverables and Demonstration

5.1 Deliverable

The project has four deliverables, where the first three deliverables are evaluated by in lab demonstrations. The deliverables are as follows:

5.1.1 RTX P1

This is the source code and documentation of a tiny kernel which provides memory management, processor management and process priority services. You need to implement

- APIs listed in Sections 2.1, 2.2 and 2.3;
- processes in Sections 3.1.1 and 3.3.1 ¹; and
- the corresponding part in Chapter 4.

5.1.2 RTX P2

This is the source code and documentation of a simplified version of the final RTX. On top of P1, you will

- add APIs listed in Sections 2.4 and 2.5;

¹Note you need to write the six user testing processes to demonstrate that your implementation meets the requirements.

- finish implementing all processes as described in Sections 3.1, 3.2 and 3.3.2;
- enhance user test processes in Section 3.3.1 so that they test this version of the kernel; and
- implement the corresponding part in Chapter 4.

5.1.3 RTX P3

This is the final RTX source code to implement the specifications in Chapters 2, 3, and 4 based on the P1 and P2 implementations done previously. To be more specific, you will

- finish implementing processes as described in Sections 3.3.3 and 3.3.4;
- enhance user test processes in Section 3.3.1 so that they test the final version of the kernel; and
- implement the corresponding part in Chapter 4.

5.1.4 RTX P4

Program a second timer on the MCB1700 board to measure the speed of primitives. Write a final project report which include the following:

- RTX Project Software Design Description: This document describes the RTX design. It should include:
 - a structural description of the design (procedures and their interconnect; data structures; processes);
 - a functional description of all procedures (pseudo code; show all input/output parameters and globals);
 - implementation, testing and measurement plan (include responsibilities of individual team members).

This part document should be kept reasonably small (no more than thirty pages, not including appendices). A design description should be shorter than the actual implementation.

- The measured times for the following primitives:
 - `send_message`,

- `receive_message` and
- `request_memory_block`,

and a check of the reasonableness of the values measured.

- A “lessons learned” summary (what you did do well, both technically and organizationally, and what you would do differently if you were to do it again). This summary should be brief (one to two pages).

The deliverable contains both the source code of the project with the timing code added in and the final report (in pdf format).

5.2 Demonstration

The first three deliverables of the project is evaluated by demonstration in the SE350 RTX Lab room.

5.2.1 Demo Reservation and Cancellation

- An on-line demo reservation link will be given to the class a couple of days before the demo.
- You may cancel a demo reservation *48 hours before* the reserved demo time slot by posting a private question on Piazza.

5.2.2 The Demo Policy

- The project is evaluated during the assigned demo time slot. It is recommended that you arrive the lab about 15 minutes earlier to set up your demo environment. The evaluation will end when the reserved demo time slot ends regardless whether you have finished demoing/answering all the items on the evaluation form or not. For the items that you are not able to finish during the reserved demo time slot, you will receive zero mark.
- During the demo of your project, your original submitted RTX implementation archive file will be retrieved and the demo will use those files in the archive. No substitutions are allowed. It is student’s responsibility to verify the submitted files are the correct version. We highly recommend to download your submission right after you submit it to confirm it is the correct version you want to submit.

- The demo is not some dry run to do additional debugging under "live" conditions. If minor bugs are discovered during the demo, depending on the complexity, you might be allowed to fix the bug, recompile and download and continue the demo. Under no circumstances will file replacements be allowed during the demo. "fixes" are basically limited to minor manual editing of a source file. Each demo for P1 and P2 is scheduled for a 30 minute slot maximum. The P3 demo slot is 55 minutes maximum. If you want to fix minor bugs, the fix needs to be finished during the reserved demo time slot.
- You are only allowed to demo once.
- ALL project group members are required to be presented during the demonstrations.

5.2.3 The Demo Procedure

P1 Demo Procedure

- **Basic Functionality Demo**
You will need to demonstrate you have successfully completed the required APIs by using your own six test processes.
- **Source Code Spot Check**
An evaluator will ask each group member implementation questions.

P2 Demo Procedure

- **Basic Functionality Demo**
You will need to demonstrate you have successfully completed the required APIs by
 - displaying the wall clock display process using various %W commands and
 - showing the output of the three hot keys.

Note you are responsible to program the six user test processes so that one process is blocked on memory and one process is blocked on receive to demonstrate the full functionality of the all the hot keys.
- **Source Code Spot Check**
An evaluator will ask each group member implementation questions.

P3 Demo Procedure

- **Basic Functionality Demo**

You will demonstrate the basic functionality of the RTX through commands line input. The evaluator will

- start, observe and stop wall clock display by using various %W commands;
- check the hot keys output; and
- set priority of processes by using %C commands.

test of wall clock display

- **Stress Test**

Your RTX will be go through a stress testing demo by using processes A, B and C. The evaluator will

- reinitialize RTX with N (N=32) envelopes, one combination of processes A,B and C priorities;
- start test process activity by %Z command;
- observe system operation (wall clock display as indicator), may also display trace buffer (is your have it implemented);

The above will be repeated with two other combinations of processes A,B and C priorities.

- **Contribution Check**

Each group member will be asked what he/she has contributed to the RTX (i.e. P1, P2 and P3) implementation.

5.2.4 Third Party Testing

We will provide third party testing object code to replace the six testing processes written by students during the demo as part of the RTX functionality testing. In order for your RTX to be able to work with the third party testing code, please refer to the files under `manual_code\AutoTest` in the GitHub repository. We provide the `rtx.h` file as shown in `manual_code\AutoTest\P1\src`. During the demo, object code will be provided to you as shown in `manual_code\P1\obj`. Note the source code of the test processes on the GitHub is for references only. During the demo, you will not be given the source code of the test processes. Only the object code will be provided to you. Your RTX will be linked with the provided object code, one at a time. To link the RTX with supplied object code.

First we will exclude the source that implemented the six test processes from the project build. Then we will add the provided object code to the linker to link with your RTX by configuring the Target Option of the project accordingly.

For example, assume that your project implements the six test user processes in the `user_proc.c` file and the `user_proc.a.o` is the object code where the six test processes are written by a third party. First we highlight the `user_proc.c` file and right click the mouse to bring up the menu. Select the options for file item (see Figure 5.1). Then you will be shown the Options for File window (see Figure 5.2). Uncheck the box beside “Include in Target Build” item to exclude the file from the final build. Click the OK button to close the window.

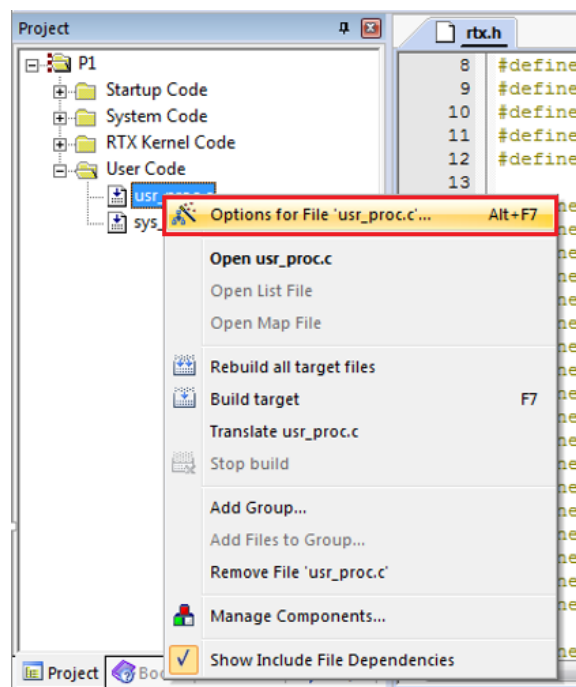

Figure 5.1: Keil IDE: Selecting File Options

Now you will see three red squares appear on the file icon of the `usr_proc.c` (see Figure 5.3). Open up the Target Option window and select the “Linker” tab. Type the third party test object code name `usr_proc.a.o` in the “Misc controls” field (see Figure 5.4). Close the target option window. We have finished the target build set up to replace the six user processes implemented in `user_proc.c` with a third party six testing processes pre-compiled in `usr_proc.o` file. You may now proceed with the build.

Part III

Design and Implementation Notes

Chapter 6

Frequently Asked Questions

We list frequently asked questions with answers in this chapter.

6.1 Processor Management

This section contains the frequently asked questions and answers of the following topics:

- context switching,
- scheduling and preemption .

6.1.1 Context Switching

Q1: In tutorial slides, it showed our processes as having 5 states: Ready, Blocked on Resource, Waiting for Message, Executing, and Interrupted. Will these five states be sufficient for our lab, or should we, for example, have a “New” state (as in the context switching sample code on GitHub)?

A1: The NEW state says a process which has never been run before is now ready to run. Tutorial slides are at a higher abstraction level. If you feel adding a new state will help you to manage the processor, then feel free to add more states. The NEW state on GitHub can be considered as a special READY state in tutorial slides.

Q2: If a process completes itself without calling `release_processor()`, should it be taken off the ready queue automatically? Should the next process be dispatched?

A2: The project requires processes never terminate (i.e. they never exit). You can keep calling the `release_processor()` after all useful actions are completed to prevent the process from terminating.

Q3: What does the `__set_MSP()` function do, and how is it able to update the program counter/link register to switch to a new process?

A3: This function sets the MSP to the value supplied. Each process has its own stack, by switching between stacks, we achieve the purpose of context switching.

Q4: How does saving/loading process contexts work in assembly code? Is there any part of the sample code which would help us understand this?

A4: You will need to use assembly code to access C data structures. Section 9.4 in the SE350 lab manual provides some code excerpts on this topic. The starter code https://github.com/yqh/SE350/blob/master/manual_code/Context_Switching/src/k_process.c shows how to context switch between two processes. Please be aware of the assumptions made at the beginning of the code comments block.

Q5: Where to put the PCB priority queues?

A5: The PCB queue structure memory can either be allocated at compile time (i.e. inside the image of your RTX) or at run time (i.e. when you do memory initialization in RTX.).

Q6: What is the initial value of PC for each process?

A5: From coding point of view, each process starts in a function. The entry point of this function (i.e. the address of this function) is the initial PC value of the process. Lines 28-29 of https://github.com/yqh/SE350/blob/master/manual_code/Context_Switching/src/usr_proc.c#L28-L29 shows an example of setting initial PC values of two user processes.

6.1.2 Scheduling and Preemption

Q1: What is preemption?

A1: Preemption in this project means when a process whose priority is higher than the priority of the current running process becomes ready, then the current process should be taken out of the processor and let the higher priority ready process to run. In other words, the preemption will guarantee a higher priority ready process will run before a lower priority ready process. It implies that if process P has higher priority than

process Q, then at any moment, the system should not allow that P is in READY state and process Q is in RUN state.

Here is a more detailed example: assume we have two processes P and Q. $\text{priority}(P) > \text{priority}(Q)$. P is blocked on some sort of resource. Q is currently running. Preemption means if an interrupt (software or hardware) happens and it results in a process (say, P) with higher priority than the current running process (say, Q) changing state to READY, then when the interrupt finishes, P will run instead of Q. We say P preempts Q.

Q2: In the project description, when it says a process *may* get preempted, does this imply preemption is not mandatory?

A2: Preemption is mandatory for the entire project and for very single deliverable. However a preemptive API call may not necessarily cause a preemption to happen because it depends on what the values you pass into the API input parameters. For example, `set_process_priority` is a preemptive call. It takes two parameters, a PID and a priority. Calling this function may or may not cause preemption depending on the values of the input parameters of this function call and priorities and states of other processes in the system. Assume we only have two processes P1 and P2. Both are at MEDIUM priority. P1 is currently in RUN state and P2 is in READY state. Example 1: P1 calls set process priority API to lower down itself to LOW priority. This case, P1 will be preempted by P2. P2 will start to RUN after the API call. Example 2: P1 calls set process priority API to increase itself to HIGH priority. This case, P1 will NOT be pre-empted by P2. P1 will continue in RUN state after the API call.

Q3: Which deliverable requires preemption to be implemented?

A3: Preemption is required for all deliverables (i.e. P1, P2 and P3).

Q4: Since we aren't using timers/interrupts in P1, I was a little unclear what sort of preemption was needed. One method we discussed having each system call call the scheduler, instead of possible returning back to the user code. Can you provide some more details on this though?

A4: Suppose a process calls `set_process_priority` to lower down its own priority, then it might be preempted due to this function call. We do not have hardware interrupts in P1, however we do have software interrupt SVC. There are other scenarios a preemption could happen as well in P1.

Q5: What is the initial priority of each process?

- A5: Except for the null process, which should be assigned a hidden priority of 4 and the I-processes where the user level priority concept does not apply, all other processes take priority levels from the range of {0, 1, 2, 3}. You decide each process's initial priority when demoing your kernel with your own test processes. You want to make your initial priority settings reasonable. For example certain priority combinations will put the system into a deadlock. Unless you want to demonstrate the deadlock as a test case, you don't select this type of initial priority settings. We will ask you to set priority of some processes to certain levels during the demo.
- Q6:** In the lab tutorial slides, four priority queues are show. Is it OK to implement the four priorities by just using one queue?
- A6: The detailed implementation is left as a free choice. So the short answer is Yes. However you may want to think about performance difference between one queue approach and the four queues approach.
- Q7: Should I always put the current running process to the back of ready queue upon a trap?**
- A7: Yes. The reason is to simplify the scheduling logic. For example, assume we have two processes that are at highest level of priority and they are P and Q. Assume P is the current running process and Q is in the ready queue. Assume P invokes the `get_process_priority` primitive, then when we trap into the kernel, P gets pushed to the back of the ready queue and Q starts to run. This seems to be unfair to P, but it makes the scheduling logic easy without compromising too much pedagogy purpose.

6.2 Memory Management

This section contains frequently asked questions regarding memory management.

Q1: Where do we allocate memory for the blocked resource queue?

- A1: Similar as the PCB queues, you could either allocate the queue in compile time (i.e. inside the image of your RTX) or at run time (i.e. when you do memory initialization in RTX). Keep in mind this only applies to the memory queue structure itself, not the nodes (i.e. the memory blocks) that the memory queue holds. The nodes are outside the RTX image.

Q2: Do we even need the block resource queue? Can't we use the array of PCBs and PROC_INIT to get blocked and priority?

A2: You are free to implement the RTX the way you want as long as the final project satisfies the required behavior of the APIs and the processes. You have the freedom to make data structure and algorithm choices, though different choices imply different performance of your RTX. Assume that you do not have a blocked on resource queue, when a certain resource becomes available, you will need to traverse the entire pcb table to find the process that is waiting for the resource and try to unblock it, this probably will be OK if you only have small number of pcbs, but will show performance problem when the number of pcbs grow.

Q3: In our request_memory_block function for the kernel, how do we know which process is requesting memory?

A3: Normally the kernel will have a global variable that points to the current running process. The Context Switching sample project names this variable `g_current_process`. So you know it is this process that is requesting the memory.

Q4: If we want to get the end of RAM, instead of hardcoding 0x10008000, can we use Image\$\$RW_IRAM1\$\$RW\$\$Limit? Or some other symbol?

A4: The end of RAM can only be hard-coded since it is tied to the specific hardware. The `Image$$RW_IRAM1$$RW$$Limit` symbol is put at the end of the Image and it should always be less than 0x10008000.

Q5: Is each stack element 8 bytes? Or is it 4 bytes?

A5: Each stack element is 4 bytes.

Q6: Why does the stack pointer need to be 8-byte aligned on ARM?

A6: The ARM Architecture Procedure Call Standard (AAPCS) requires stack to be double-word aligned at a public interface. The AAPCS is posted in Learn under manufacture manual section for your reference.

Q7: I'm looking at k_memory.c. What are these 8-byte alignment shenanigans?

```
U32 *gp_stack;
/* code to initialize gp_stack skipped */
if ((U32)gp_stack & 0x04) { /* 8 bytes alignment */
    --gp_stack;
}
```

A7: The code basically checks whether the `gp_stack` is aligned by four bytes (i.e. bit AND with binary 100), but not aligned by eight bytes. If yes, then decrement it by four bytes to make it eight bytes aligned. The `gp_stack` is a U32 *, the compiler will give it an address of four bytes aligned. So it is either eight bytes aligned or not eight bytes aligned, but always four bytes aligned. Because it is U32 *, pointer arithmetic `gp_stack` decrements it by four bytes and we get eight byte alignment.

Q8: How do we assign a memory block to a PCB?

A8: When a process (say process P) invokes `release_memory_block` primitive, if there are processes that are blocked on memory, then the OS should allocate this memory block to the highest waiting-for-memory process that waited longest (say process Q) instead of putting the memory block back to the pool. This results in changing the state of Q to ready and move Q from the blocked queue to the ready queue. However this may not necessarily mean P will be switched out and Q will start to run. After you put Q into the ready queue, the schedule will make the scheduling decision and select the next to run process. It could be P, it could be Q and it even could be some other ready processes that is in the same priority level as P. One way is to have some variable defined in PCB to remember this piece of memory block. Other approaches exist.

Q9: How big is each memory block and how many memory blocks are there?

A9: The minimum size of each memory block is 128 bytes (see Section 2.1). During your development, you decide how many memory blocks the RTX can manage. At minimum, your RTX should be able to manage 32 memory blocks (see Section 5.2.3).

6.3 Interprocess Communication (IPC)

Q1: What is a message envelope?

A1: The project requires a message-based IPC scheme. Messages are carried in shared memory blocks. A process writes a message into a shared memory block, sends a pointer to the memory block to another process and receiving process reads the message from the memory block. A shared memory block used for message passing is a “message envelope”.

Q2: What is the format of the message envelope?

A2: The message envelope contains two data structures. One is for the kernel management purpose. The kernel is supposed to write to this data structure. For example it

may contain some linked list pointers, sender PID, receiver PID and other kernel data. This data structure can be either put in the kernel space or user space. The compilation macro `K_MSG_ENV` controls whether the OS wants to expose this data structure to the user space or not. The second data structure is exposed to user space. It contains the message type and the actual message body. The `struct msgbuf` data structure is defined in Section 2.4. See Q1 in Section 6.6 on how to use the Keil IDE to define compilation macros.

Q3: Where does the message envelope come from and how does user process use it to send a message?

A3: The user process calls `request_memory_block` primitive to request a memory block to be used as a message envelope and the user will start to fill the `struct msgbuf` non-kernel data structure defined in Section 2.4. For example, the following user process (wall clock process) code will send a command registration message to process KCD (Keyboard Command Decoder).

```
struct msgbuf *p_msg_env = (struct msgbuf *) request_memory_block();
p_msg_env->mtype = KCD_REG;
p_msg_env->mtext[0] = '%';
p_msg_env->mtext[1] = 'W';
p_msg_env->mtext[2] = '\0';
send_message(PID_KCD, (void *)p_msg_env);
```

Q4: The lab manual has the following structure:

```
struct msgbuf {
#ifdef K_MSG_ENV
    void *mp_next;    /* ptr to the next message */
    int m_send_pid;   /* sender pid */
    int m_recv_pid;   /* receiver pid */
    int m_kdata[5];   /* extra 20B kernel data place holder */
#endif
    int mtype;        /* user defined message type */
    char mtext[1];    /* body of the message */
};
```

The slides have something like this

```
msg t (an envelope) {
```

```
next message
Sender PID
Destination PID
Message Type
Message Data
};
```

which one is correct?

A4: The slides give you one possible message envelope data structure as an example to illustrate the idea of a message envelop. The example in slides exposes kernel data structure to user space. The manual uses the compilation macro `K_MSG_ENV` to expose the next message, Sender PID and Destination PID fields to the user process view. If you want to hide these fields in the kernel, then do not define the compilation macro and instead find some kernel memory space to save these data. The manual specification makes it possible to hide more information from the view of a user process by using a compilation macro of `K_MSG_ENV`. See Q1 in Section 6.6 on how to use the Keil IDE to define compilation macros.

Q5: The definitions of `receive_message()` are different:

```
Manual: void *receive_message(int *sender_id);
Slides: msg_t receive_message();
```

which one is correct?

A5: Follow the specification in the manual. Sorry that we missed this piece of outdated information in the slides.

6.4 Processes

6.4.1 The Six User Test Processes

Q1: Do we need to write testing cases to test the six test processes?

A1: The purpose of the user test processes is to implement test cases at user level to test the OS APIs your kernel provides. You do not really test the test processes.

Q2: Does each user test process implement one test case/scenario?

A2: No. Some test scenarios may require more than one test process. One example is to test a process to be blocked on memory when the system is out of memory. This scenario cannot be tested with just one process.

6.4.2 System Processes

Q1: Is system process a kernel process or user process?

A1: A system process can run as a user process or a kernel process depending what the system process is doing and what resources it needs.

Q2: Where should we put the null process (which file)?

A2: Where to put the process in a file is up to you. You have the sole freedom to organize the code in this project. To facilitate the automated third-party user level testing, you should not put the null process in the same file where you define the six user test processes.

Q3: Are system processes such as KCD and CRT scheduled the same as user processes?

A3: Yes.

Q4: Does the sample interrupt-driven UART code include any mechanism for calling our keyboard/CRT routines on interrupt? Or do we need to write that ourselves?

A4: The provided sample UART IRQ code contains both receive and transmit interrupts handling logic. You can borrow the relevant part of the code to write your own CRT, KCD and I-process code.

6.4.3 The I-processes

Q1: Why does an I-process need a pcb?

A1: Because the RTX uses message passing to request interrupt related services and the I-process needs at least a process ID to facilitate this.

Q2: How to invoke an I-process?

A2: The I-process is triggered (or scheduled) by interrupts. When an interrupt fires, it goes to the specific IRQ service routine and this service routine will need to save the context of the current running process (say P) and then makes the code that implement the I-process (most likely a function) to run. Once the I-process finishes, the scheduler may pick another process to run (say Q, P and Q may not necessarily be the same) and the context of Q needs to be restored properly.

There are still context switching involved, but due to the special two state property of an I-process, some students may choose not to do a full fledged context switching as a normal process would do to run the I-process. The bottom line is that an I-process does not get interrupted and the process before the I-process and after the I-process need to have context saved and restored properly.

Q3: Do we need to save the context of the I-process and restore it later?

A3: An i-process only has two states: RUN or WAITING_FOR_INTERRUPT. It does not get interrupted, so there is no need to save or restore i-process's context. But there is a need to save the context of the process that gets interrupted by the I-process and restore the context of the process that the system decides to run after the I-process finishes.

Q4: To get the interrupt processes to act immediately, I am considering giving them a process priority of -1 so that the scheduler gives interrupt processes the highest priority. This would allow a smooth integration of these processes into the current OS. One of the functions that we must have is `get_process_priority(int processID)` returns -1 on error, and just above that, it says process' can only have priority of 0 - 4. Is this function only expected to work for user processes, thus our solution is viable? Or are we not allowed to use the priority of -1 as specified by the 0-4 range for some reason?

A4: The project specification requires when a user process calls `get_process_priority`, the function returns -1 on error. If you want to have "-1" as a valid process priority for special processes such as i-process, then you have to hide this fact from regular user process. The i-process is *scheduled* by the interrupt, so technically it by-passes the regular process scheduler. However some students in the past did implement the i-process invocation by giving it the highest priority in the system. As long as your implementation follows the specification, we accepted it.

Q5: When an I-process use message passing to send data to the KCD and CRT process, that means they have to request a memory block. What happens if there is no memory in the system? An I-process cannot be memory blocked so should we just disregard that particular interrupt?

A5: In the project description, it mentioned to adapt the behaviour of blocking primitives when they are called by an I-process. You should never let an I-process be blocked.

6.5 Interrupts

Q1: Do we need to use `atomic(on)` and `atomic(off)` for the RTX P1 deliverable. If yes can you explain how atomic works?

A1: In sense of this project, the `atomic(on)` turns off all interrupts and `atomic(off)` turns on all interrupts. For P1, we assume there is no interrupts, so no need for atomicity for P1. But they are needed in P2 and P3.

Q2: Why do we need to call the scheduler at the end of an interrupt handling process? Wouldn't simply going back to the previously running process work?

A2: The reason is that an interrupt may cause a preemption. For example, if you have a higher priority process blocked on receiving a message that is sent by `delayed_send()` primitive. A timer interrupt may cause the message to be delivered to this higher priority process. Hence when the interrupt finishes, you should not return to the previous process which has lower priority.

Q3: What should the correct behaviour be when a new interrupt happens while handling a previous interrupt?

A3: In this project, nested interrupt is not required. You could just disable all interrupts when you are inside the interrupt handler.

Q4: How to enable and disable all interrupts?

A4: This can be done either in the assembly code or the C code. Please see table 9.3.

Q5: Is the TX interrupt activated by setting the TX FIFO rest bit specified in Table 278 on p305 of LPC17xx user's manual[4]?

A5: It is the THRE Interrupt Enable bit in Table 275 on page 302.

6.6 Keil IDE

Q1: Is there a way we can have two configurations, one for debug and one for release? This way we can have a `DEBUG` macro be defined only in

the debug configuration.I noticed you use DEBUG_0. Is this some special macro?

A1: The conditional compilation symbol `DEBUG_0` is defined in target options under C/C++ tab. This is a symbol we define for debugging purpose which makes the code to print out more debugging messages. You could define your own symbol to control compilation in a similar way.

Q2: Is it possible to trigger UART interrupts via the keyboard while debugging with the simulator?

A2: Yes, just type in the `UART#1` window in simulator (assuming you are programming `UART0`). If you are looking at the sample UART IRQ code on GitHub, you need to work on the SIM target in order to see IRQs under simulator. Not the RAM target.

Q3: How to enable c99?

A3: In the target option, activate the C/C++ tab. Enter `--c99` in the Misc Controls text field.

Part IV

Keil MCB1700 Quick Reference Guide

Chapter 7

Keil MCB1700 Hardware Environment

7.1 MCB1700 Board Overview

The Keil MCB1700 board is populated with *NXP LPC1768* Microcontroller. Figure 7.1 shows the important interface and hardware components of the MCB1700 board.

Figure 7.2 is the hardware block diagram that helps you to understand the MCB1700 board components. Note that our lab will only use a small subset of the components which include the LPC1768 CPU, COM and Dual RS232.

The LPC1768 is a 32-bit ARM Cortex-M3 microcontroller for embedded applications requiring a high level of integration and low power dissipation. The LPC1768 operates at up to an 100 MHz CPU frequency. The peripheral complement of LPC1768 includes 512KB of on-chip flash memory, 64KB of on-chip SRAM and a variety of other on-chip peripherals. Among the on-chip peripherals, there are system control block, pin connect block, 4 UARTs and 4 general purpose timers, some of which will be used in your RTX course project. Figure 7.3 is the simplified LPC1768 block diagram [4], where the components to be used in your RTX project are circled with red. Note that this manual will only discuss the components that are relevant to the RTX course project. The LPC17xx User Manual is the complete reference for LPC1768 MCU.

7.2 Cortex-M3 Processor

The Cortex-M3 processor is the central processing unit (CPU) of the LPC1768 chip. The processor is a 32-bit microprocessor with a 32-bit data path, a 32-bit register bank, and

Figure 7.1: MCB1700 Board Components [1]

Figure 7.2: MCB1700 Board Block Diagram [1]

Figure 7.3: LPC1768 Block Diagram

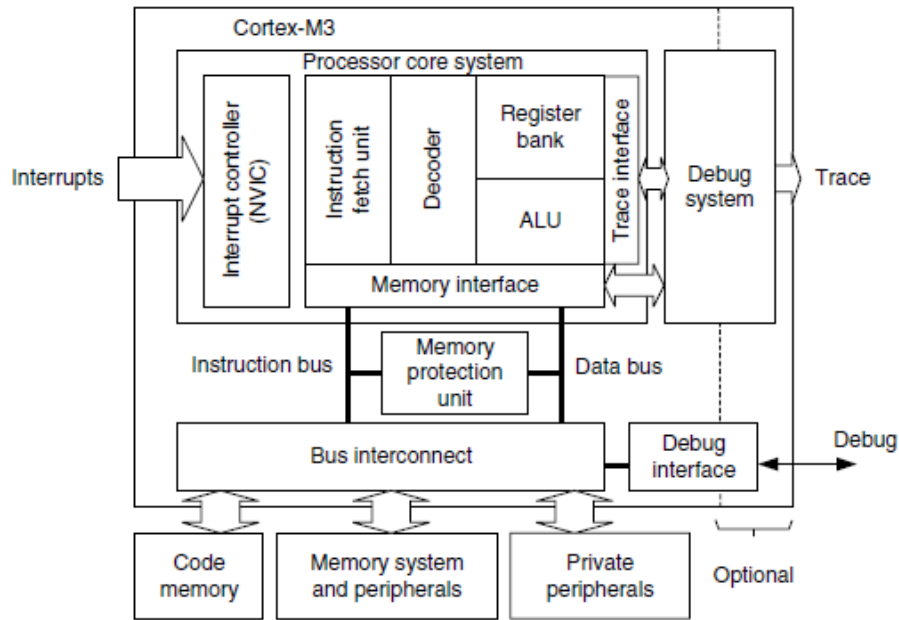

Figure 7.4: Simplified Cortex-M3 Block Diagram[5]

32-bit memory interfaces. Figure 7.4 is the simplified block diagram of the Cortex-M3 processor [5]. The processor has private peripherals which are system control block, system timer, NVIC (Nested Vectored Interrupt Controller) and MPU (Memory Protection Unit). The MPU programming is not required in the course project. The processor includes a number of internal debugging components which provides debugging features such as breakpoints and watchpoints.

7.2.1 Registers

The processor core registers are shown in Figure 7.5. For detailed description of each register, Chapter 34 in [4] is the complete reference.

- R0-R12 are 32-bit general purpose registers for data operations. Some 16-bit Thumb instructions can only access the low registers (R0-R7).
- R13(SP) is the stack pointer alias for two banked registers shown as follows:
 - *Main Stack Pointer (MSP)*: This is the default stack pointer and also reset value. It is used by the OS kernel and exception handlers.
 - *Process Stack Pointer (PSP)*: This is used by user application code.

Figure 7.5: Cortex-M3 Registers[4]

On reset, the processor loads the MSP with the value from address 0x00000000. The lowest 2 bits of the stack pointers are always 0, which means they are always word aligned.

In Thread mode, when bit[1] of the CONTROL register is 0, MSP is used. When bit[1] of the CONTROL register is 1, PSP is used.

- R14(LR) is the link register. The return address of a subroutine is stored in the link register when the subroutine is called.
- R15(PC) is the program counter. It can be written to control the program flow.
- Special Registers are as follows:
 - Program Status registers (PSRs)
 - Interrupt Mask registers (PRIMASK, FAULTMASK, and BASEPRI)
 - Control register (CONTROL)

When at privilege level, all the registers are accessible. When at unprivileged (user) level, access to these registers are limited.

7.2.2 Processor mode and privilege levels

The Cortex-M3 processor supports two modes of operation, Thread mode and Handler mode.

- Thread mode is entered upon Reset and is used to execute application software.
- Handler mode is used to handle exceptions. The processor returns to Thread mode when it has finished exception handling.

Software execution has two access levels, Privileged level and Unprivileged (User) level.

- Privileged
The software can use all instructions and has access to all resources. Your RTOS kernel functions are running in this mode.
- Unprivileged (User)
The software has limited access to **MSR** and **MRS** instructions and cannot use the **CPS** instruction. There is no access to the system timer, NVIC , or system control block. The software might also have restricted access to memory or peripherals. User processes such as the wall clock process should run at this level.

When the processor is in Handler mode, it is at the privileged level. When the processor is in Thread mode, it can run at privileged or unprivileged (user) level. The bit[0] in **CONTROL** register determines the execution privilege level. Figure 7.6 illustrate the mode and privilege level of the processor.

Figure 7.6: Cortex-M3 Operating Mode and Privilege Level[5]

Note that only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the

SVC instruction to make a supervisor call to transfer control to privileged software. Another way to change between Privileged Thread mode and Unprivileged thread mode is to modify the EXC_RETURN value in the LR (R14) when returning from an exception. You probably want to use this mechanism for context switching.

7.2.3 Stacks

The processor uses a full descending stack. This means the stack pointer indicates the last stacked item on the stack memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location.

The processor implements two stacks, the *main stack* and the *process stack*. One of these two stacks is banked out depending on the stack in use. This means only one stack is visible at a time as R13. In Handler mode, the main stack is always used. The bit[1] in CONTROL register reads as zero and ignores writes in Handler mode. In Thread mode, the bit[1] setting in CONTROL register determines whether the main stack or the process stack is currently used. Table 7.1 summarizes the processor mode, execution privilege level, and stack use options.

Processor mode	Used to execute	Privilege level for software execution	CONTROL		Stack used
			Bit[0]	Bit[1]	
Thread	Applications	Privileged	0	0	Main Stack
		Unprivileged	1	1	Process Stack
Handler	Exception handlers	Privileged	-	0	Main Stack

Table 7.1: Summary of processor mode, execution privilege level, and stack use options

7.3 Memory Map

The Cortex-M3 processor has a single fixed 4GB address space. Table 7.2 shows how this space is used on the LPC1768.

Note that the memory map is not continuous. For memory regions not shown in the table, they are reserved. When accessing reserved memory region, the processor's behavior is not defined. All the peripherals are memory-mapped and the LPC17xx.h file defines the data structure to access the memory-mapped peripherals in C.

Address Range	General Use	Address range details	Description
0x0000 0000 to 0x1FFF FFFF	On-chip non-volatile memory	0x0000 0000 – 0x0007 FFFF	512 KB flash memory
	On-chip SRAM	0x1000 0000 – 0x1000 7FFF	32 KB local SRAM
	Boot ROM	0x1FFF 0000 – 0x1FFF 1FFF	8 KB Boot ROM
0x2000 0000 to 0x3FFF FFFF	On-chip SRAM	0x2007 C000 – 0x2007 FFFF	AHB SRAM - bank0 (16 KB)
	(typically used for peripheral data)	0x2008 0000 – 0x2008 3FFF	AHB SRAM - bank1 (16 KB)
	GPIO	0x2009 C000 – 0x2009 FFFF	GPIO
0x4000 0000 to 0x5FFF FFFF	APB Peripherals	0x4000 0000 – 0x4007 FFFF	APB0 Peripherals
		0x4008 0000 – 0x400F FFFF	APB1 Peripherals
	AHB peripherals	0x5000 0000 – 0x501F FFFF	DMA Controller, Ethernet interface, and USB interface
0xE000 0000 to 0xE00F FFFF	Cortex-M3 Private Peripheral Bus (PPB)	0xE000 0000 – 0xE00F FFFF	Cortex-M3 private registers(NVIC, MPU and SysTick Timer et. al.)

Table 7.2: LPC1768 Memory Map

7.4 Exceptions and Interrupts

The Cortex-M3 processor supports system exceptions and interrupts. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. The processor uses *Handler mode* to handle all exceptions except for reset.

7.4.1 Vector Table

Exceptions are numbered 1-15 for system exceptions and 16 and above for external interrupt inputs. LPC1768 NVIC supports 35 vectored interrupts. Table 7.3 shows system exceptions and some frequently used interrupt sources. See Table 50 and Table 639 in [4] for the complete exceptions and interrupts sources. On system reset, the vector table is fixed at address 0x00000000. Privileged software can write to the VTOR (within the System Control Block) to relocate the vector table start address to a different memory location, in the range 0x00000080 to 0x3FFFFFFF80.

7.4.2 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either

- the processor is in Thread mode

Exception number	IRQ number	Vector address or offset	Exception type	Priority	C PreFix
1	-	0x00000004	Reset	-3, the highest	
2	-14	0x00000008	NMI	-2,	NMI_
3	-13	0x0000000C	Hard fault	-1	HardFault_
4	-12	0x00000010	Memory management fault	Configurable	MemManage_
⋮					
11	-5	0x0000002C	SVCall	Configurable	SVC_
⋮					
14	-2	0x00000038	PendSV	Configurable	PendSVC_
15	-1	0x0000003C	SysTick	Configurable	SysTick_
16	0	0x00000040	WDT	Configurable	WDT_IRQ
17	1	0x00000044	Timer0	Configurable	TIMER0_IRQ
18	2	0x00000048	Timer1	Configurable	TIMER1_IRQ
19	3	0x0000004C	Timer2	Configurable	TIMER2_IRQ
20	4	0x00000050	Timer3	Configurable	TIMER3_IRQ
21	5	0x00000054	UART0	Configurable	UART0_IRQ
22	6	0x00000058	UART1	Configurable	UART1_IRQ
23	7	0x0000005C	UART2	Configurable	UART2_IRQ
24	8	0x00000060	UART3	Configurable	UART3_IRQ
⋮					

Table 7.3: LPC1768 Exception and Interrupt Table

- the processor is in Handler mode and the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception (This is the nested exception case which is not required in our RTOS lab).

When an exception takes place, the following happens

- Stacking

When the processor invokes an exception (except for tail-chained or a late-arriving exception, which are not required in the RTOS lab), it automatically stores the following eight registers to the SP:

- R0-R3, R12
- PC (Program Counter)
- PSR (Processor Status Register)
- LR (Link Register, R14)

Figure 7.7 shows the exception stack frame. Note that by default the stack frame is aligned to double word address starting from Cortex-M3 revision 2. The alignment feature can be turned off by programming the STKALIGN bit in the System Control Block (SCB) Configuration Control Register (CCR) to 0. On exception entry, the processor uses bit[9] of the stacked PSR to indicate the stack alignment. On return from the exception, it uses this stacked bit to restore the correct stack alignment.

Figure 7.7: Cortex-M3 Exception Stack Frame [5]

- Vector Fetching

While the data bus is busy stacking the registers, the instruction bus fetches the exception vector (the starting address of the exception handler) from the vector table. The stacking and vector fetch are performed on separate bus interfaces, hence they can be carried out at the same time.

- Register Updates

After the stacking and vector fetch are completed, the exception vector will start to execute. On entry of the exception handler, the following registers will be updated as follows:

- SP: The SP (MSP or PSP) will be updated to the new location during stacking. Stacking from the privileged/unprivileged thread to the first level of the exception handler uses the MSP/PSP. During the execution of exception handler routine, the MSP will be used when stack is accessed.
- PSR: The IPSR will be updated to the new exception number

- PC: The PC will change to the vector handler when the vector fetch completes and starts fetching instructions from the exception vector.
- LR: The LR will be updated to a special value called **EXC_RETURN**. This indicates which stack pointer corresponds to the stack frame and what operation mode the processor was in before the exception entry occurred.
- Other NVIC registers: a number of other NVIC registers will be updated .For example the pending status of exception will be cleared and the active bit of the exception will be set.

7.4.3 EXC_RETURN Value

EXC_RETURN is the value loaded into the LR on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The **EXC_RETURN** bits [31 : 4] is always set to 0xFFFFFFFF by the processor. When this value is loaded into the PC, it indicates to the processor that the exception is complete and the processor initiates the exception return sequence. Table 7.4 describes the **EXC_RETURN** bit fields. Table 7.5 lists Cortex-M3 allowed **EXC_RETURN** values.

Bits	31:4	3	2	1	0
Description	0xFFFFFFFF	Return mode (Thread/Handler)	Return stack	Reserved; must be 0	Process state (Thumb/ARM)

Table 7.4: **EXC_RETURN** bit fields [5]

Value	Description		
	Return Mode	Exception return gets state from	SP after return
0xFFFFFFFF1	Handler	MSP	MSP
0xFFFFFFFF9	Thread	MSP	MSP
0xFFFFFFFFD	Thread	PSP	PSP

Table 7.5: **EXC_RETURN** Values on Cortex-M3

7.4.4 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the **EXC_RETURN** value into the PC:

- a POP instruction that includes the PC. This is normally used when the `EXC_RETURN` in LR upon entering the exception is pushed onto the stack.
- a BX instruction with any register. This is normally used when LR contains the proper `EXC_RETURN` value before the exception return, then BX LR instruction will cause an exception return.
- a LDR or LDM instruction with the PC as the destination. This is another way to load PC with the `EXC_RETURN` value.

Note unlike the ColdFire processor which has the `RTE` as the special instruction for exception return, in Cortex-M3, a normal return instruction is used so that the whole interrupt handler can be implemented as a C subroutine.

When the exception return instruction is executed, the following exception return sequences happen:

- Unstacking: The registers (i.e. exception stack frame) pushed to the stack will be restored. The order of the POP will be the same as in stacking. The SP will also be changed back.
- NVIC register update: The active bit of the exception will be cleared. The pending bit will be set again if the external interrupt is still asserted, causing the processor to reenter the interrupt handler.

7.5 Data Types

The processor supports 32-bit words, 16-bit halfwords and 8-bit bytes. It supports 64-bit data transfer instructions. All data memory accesses are managed as little-endian.

Chapter 8

Keil Software Development Tools

The Keil MDK-ARM development tools are used for MCB1700 boards in our lab. The tools include

- μ Vision4 IDE which combines the project manager, source code editor and program debugger into one environment;
- ARM compiler, assembler, linker and utilities;
- ULINK USB-JTAG Adapter which allows you to debug the embedded programs running on the board.

The MDK-Lite is the evaluation version and does not require a license. However it has a code size limit of 32KB, which is adequate for your course projects. The MDK-Lite version 4.60.0.0 ¹ is installed on all lab computers. If you want to install the software on your own computer, Appendix A gives detailed instruction.

8.1 Creating an Application in μ Vision4 IDE

To get started with the Keil IDE, the MDK-ARM Primer

<http://www.keil.com/support/man/docs/gsac/>

is a good place to start. We will walk you through the IDE by developing a simple HelloWorld application which displays Hello World through the UART0 that is connected to the lab PC. Note the HelloWorld example uses polling rather than interrupt.

¹The latest version is 5.1.0.0 We have not fully tested the supplied sample code with this version. This manual is based on version 4.60.0.0.

8.1.1 Create a New Project

Open the file explorer and navigate to `C:\Software\Keil\UV4`. Double click the `Uv4.exe` program to start the IDE.

1. Create a folder named “HelloWorld” on your computer ².
2. Copy the following files to “HelloWorld” folder:
 - `manual_code\UART_polling\src\uart_polling.h`
 - `manual_code\UART_polling\src\uart_polling.c`
 - `manual_code\Startup\system_LPC17xx.c`
3. Create a new μ Vision project by click
 - Project \rightarrow New μ Vision Project (See Figure 8.1)

Figure 8.1: Keil IDE: Create a New Project

- Choose NXP(Founded by Philips) \rightarrow LPC1768 (See Figure 8.2(a) and Figure 8.2(b))
- Answer “Yes” to copy the startup code (See Figure 8.3).

8.1.2 Managing Project Components

You just finished creating a new project. On the left side of the IDE is the Project window and expand all objects, you will see the default project setup as shown in Figure 8.4.

1. Rename the Target
The “Target 1” is the default name of the project build target and you can rename it by clicking the target name to highlight it and then click the highlighted name to input a new target name, say “HelloWorld SIM”

²The folder path name should not contain spaces on Nexus computers.

Figure 8.2: Keil IDE: Choose MCU

Figure 8.3: Keil IDE: Copy Startup Code

2. Rename the Source Group

The IDE allows you to group source files to different groups to better manage the source code. By default “Source Group 1” is created and the startup code “startup_LPC17xx.s” is put under this source group. You can rename the source group by clicking the source group name to highlight it and then click again to input a new name, say “Startup Code”.

3. Add a New Source Group

You can add new source groups to your project. Click “Project → Manage” → “Components, Environment, Books...” (See Figure 8.5 You can now add new source groups to the project. Let’s add “System Code” and “Source Code” source groups to the project (See Figure 8.6. Your project will now look like Figure 8.7

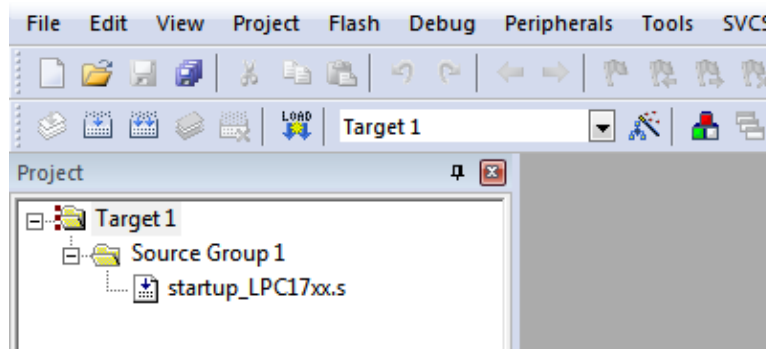

Figure 8.4: Keil IDE: A default new project

Figure 8.5: Keil IDE: Manage Project Components

Figure 8.6: Keil IDE: Manage Components Window

4. Add Source Code to a Source Group

Now add “system_LPC17xx.c” to “System Code” group by double clicking the source group and choose the file from the file window. Double clicking the file name will add the file to the source group. Or you can select the file and click the “Add” button at the lower right corner of the window (See Figure 8.8).

Similarly, add “uart_polling.c” to “Source Code” group. Your project will now look like Figure 8.9.

5. Create a new source file

The project does not have a main function yet. We now create a new file by clicking the “New” button (See Figure 8.10). Before typing anything to the file, save the file

Figure 8.7: Keil IDE: Updated Project Profile

Figure 8.8: Keil IDE: Add Source File to Source Group

and name it “main.c”. Put the following code to the main.c file:

```
#include <LPC17xx.h>
#include "uart_polling.h"
int main() {
    SystemInit();
    uart0_init();
    uart0_put_string("Hello World!\n\r");
    return 0;
}
```

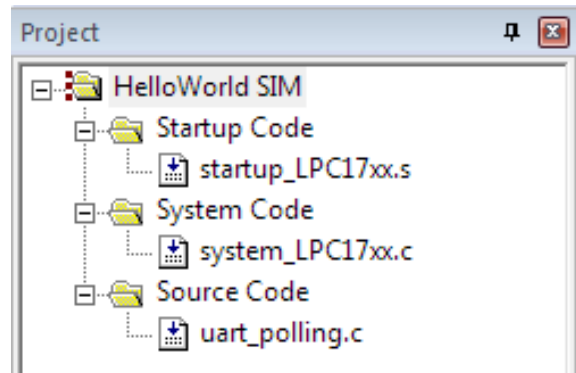

Figure 8.9: Keil IDE: Updated Project Profile

Figure 8.10: Keil IDE: Create New File

}

Then add main.c to the “Source Code” group. Your final project would look like the screen shot in Figure 8.11.

Figure 8.11: Keil IDE: Final Project Setting

8.1.3 Build and Download

To build the target, click the “Build” button (see Figure 8.12). If nothing is wrong, the

Figure 8.12: Keil IDE: Build Target

build output window at the bottom of the IDE will show a log similar like the one shown in Figure 8.13

Figure 8.13: Keil IDE: Build Target

To download the code to the board, click the “Load” button (see Figure 8.14). The download is through the Ulink-Me.

You will need a terminal emulator such as PuTTY that talks directly to COM ports in order to see output of the serial port. To find out the two COM ports, open up the device manager and expand the Ports (COM & LPT) line (see Figure 8.15). An example PuTTY Serial configuration is shown in Figures 8.16(a) and 8.16(b). Press the Reset button on the board and you should see “Hello World!” displayed on PuTTY.

Figure 8.14: Keil IDE: Download Target to Flash

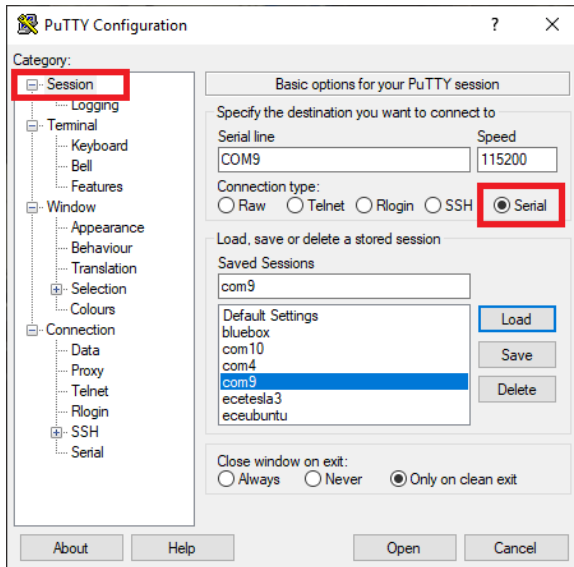

Figure 8.15: Device Manger COM Ports

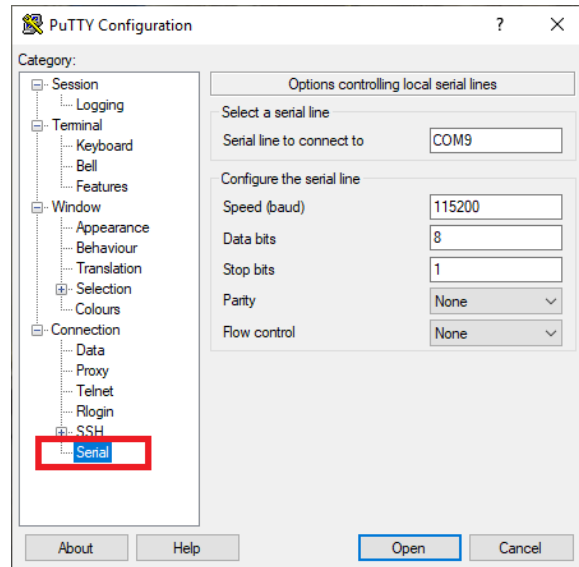

8.2 Debugging

You can use either the simulator within the IDE or the ULINK Cortex Debugger to debug your program. To start a debug session, click Debug→Start/Stop Debug Session from the IDE menu bar or press Ctrl+F5. Figure 8.16 shows the a typical debug session interface.

As any other GUI debugger, the IDE allows you to set up break points and step through your source code. It also shows the registers, which is very helpful for debugging low level code. Click View, Debug and Peripherals from the IDE menu bar and explore the functionality of the debugger.

(a) PuTTY Session for Serial Port Communication

(b) PuTTY Serial Port Configuration

8.2.1 Simulation

Most of the development normally is done under the simulation mode. The default setting of the project uses the simulator to debug as shown in the target option (see Figure 8.17). Instead of load the program to the board for execution, you can run the code using the debugger under simulation mode.

8.2.2 Configure In-Memory Execution Using ULINK Cortex Debugger

When you debug hardware related problems, you most likely will find the ULINK Cortex Debugger is helpful. You need to configure the debugger as shown in Figure 8.18.

The default image memory map setting is that the code is executed from the ROM (see Figure 8.19(a)). Since the ROM portion of the code needs to be flashed in order to be executed on the board, this incurs wear-and-tear on the on-chip flash of the LPC1768. Since most attempts to write a functioning RTX will eventually require some more or less elaborate debugging, the flash memory might wear out quickly. Unlike the flash memory stick file systems where the wear is aimed to be uniformly distributed across the memory portion, this flash memory will get used over and over again in the same portion.

The ARM compiler can be configured to have a different starting address. We can create a RAM target where the code starting address is in RAM (see Figure 8.19(b)). An

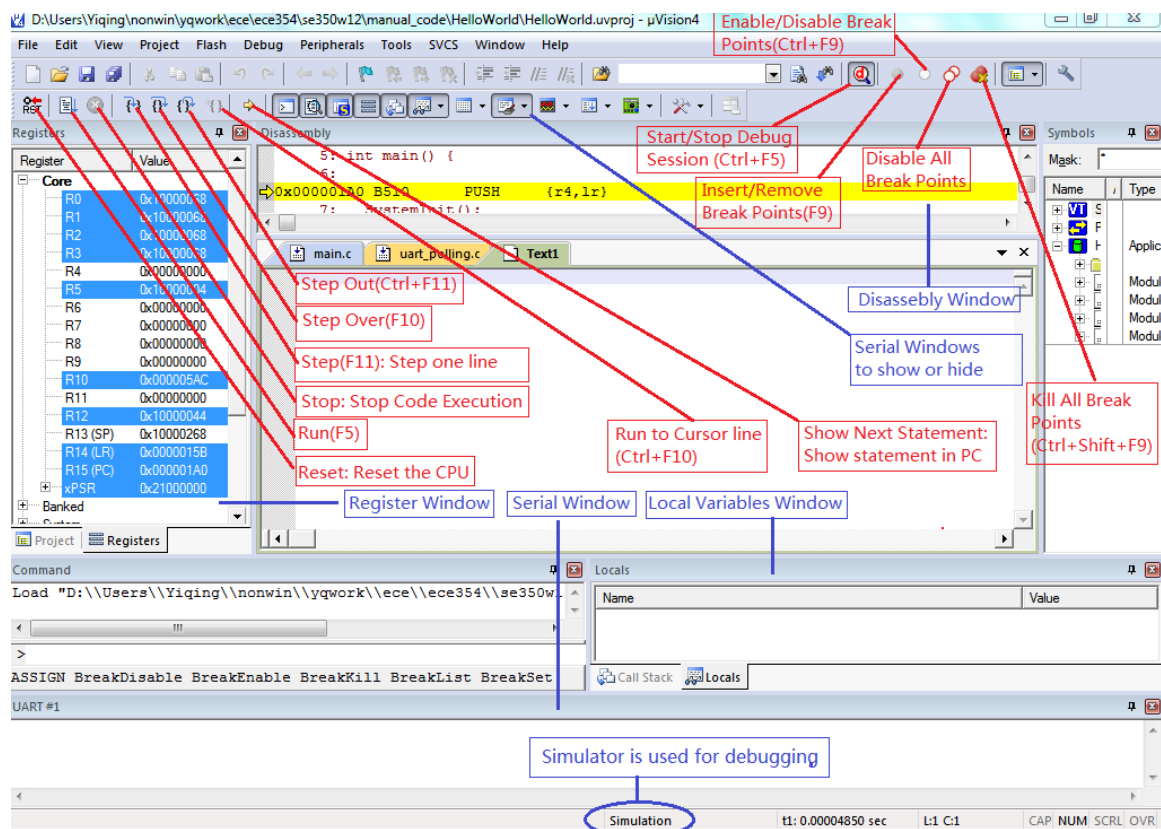

Figure 8.16: Keil IDE: Debugging

initialization file `RAM.ini` (see Listing 8.1) is needed to do the proper setting of SP, PC and vector table offset register.

```

FUNC void Setup (void) {
    SP = _RDWORD(0x10000000);           // Setup Stack Pointer
    PC = _RDWORD(0x10000004);           // Setup Program Counter
    _WDWORD(0xE000ED08, 0x10000000);    // Setup Vector Table
    Offset Register
}
// You need to provide the path of the .axf file here
LOAD build\RAM\HelloWorld.axf INCREMENTAL // Download
Setup();                                // Setup for Running
g, main

```

Listing 8.1: The `RAM.ini` file

To download the code to the board, one should not use the download button. Instead, the debug button is used to initiate a debug session and the `RAM.ini` file will load the code

Figure 8.17: Keil IDE: Using Simulator for Debugging

to the board.

Chapter 9

Programming MCB1700

9.1 The Thumb-2 Instruction Set Architecture

The Cortex-M3 supports only the Thumb-2 (and traditional Thumb) instruction set. With support for both 16-bit and 32-bit instructions in the Thumb-2 instruction set, there is no need to switch the processor between Thumb state (16-bit instructions) and ARM state (32-bit instructions).

In the RTOS lab, you will need to program a little bit in the assembler language. We introduce a few assembly instructions that you most likely need to use in your project in this section.

The general formatting of the assembler code is as follows:

```
label
    opcode operand1, operand2, ... ; Comments
```

The `label` is optional. Normally the first operand is the destination of the operation (note `STR` is one exception).

Table 9.1 lists some assembly instructions that the RTX project may use. For complete instruction set reference, we refer the reader to Section 34.2 (ARM Cortex-M3 User Guide: Instruction Set) in [4].

9.2 ARM Architecture Procedure Call Standard (AAPCS)

The AAPCS (ARM Architecture Procedure Call Standard) defines how subroutines can be separately written, separately compiled, and separately assembled to work together. The

Mnemonic	Operands/Examples	Description
LDR	<i>Rt</i> , [<i>Rn</i> , # <i>offset</i>] LDR R1, [R0, #24]	Load Register with word Load word value from an memory address R0+24 into R1
LDM	<i>Rn</i> {!}, <i>reglist</i> LDM R4, {R0 – R1}	Load Multiple registers Load word value from memory address R4 to R0, increment the address, load the value from the updated address to R1.
STR	<i>Rt</i> , [<i>Rn</i> , # <i>offset</i>] STR R3, [R2, R6] STR R1, [SP, #20]	Store Register word Store word in R3 to memory address R2+R6 Store word in R1 to memory address SP+20
MRS	<i>Rd</i> , <i>spec_reg</i> MRS R0, MSP MRS R0, PSP	Move from special register to general register Read MSP into R0 Read PSP into R0
MSR	<i>spec_reg</i> , <i>Rm</i> MSR MSP, R0 MSR PSP, R0	Move from general register to special register Write R0 to MSP Write R0 to PSP
PUSH	<i>reglist</i> PUSH {R4 – R11, LR}	Push registers onto stack push in order of decreasing the register numbers
POP	<i>reglist</i> POP {R4 – R11, PC}	Pop registers from stack pop in order of increasing the register numbers
BL	<i>label</i> BL funC	Branch with Link Branch to address labeled by funC, return address stored in LR
BLX	<i>Rm</i> BLX R12	Branch indirect with link Branch with link and exchange (Call) to an address stored in R12
BX	<i>Rm</i> BX LR	Branch indirect Branch to address in LR, normally for function call return

Table 9.1: Assembler instruction examples

C compiler follows the AAPCS to generate the assembly code. Table 9.2 lists registers used by the AAPCS.

Register	Synonym	Special	Role in the procedure call standard
r15		PC	The Program Counter.
r14		LR	The Link Register.
r13		SP	The Stack Pointer (full descending stack).
r12		IP	The Intra-Procedure-call scratch register.
r11	v8		Variable-register 8.
r10	v7		Variable-register 7.
r9		v6	Platform register.
		SB	The meaning of this register is defined by platform standard.
		TR	
r8	v5		Variable-register 5.
r7	v4		Variable-register 4.
r6	v3		Variable-register 3.
r5	v2		Variable-register 2.
r4	v1		Variable-register 1.
r3	a4		argument / scratch register 4
r2	a3		argument / scratch register 3
r1	a2		argument / result / scratch register 2
r0	a1		argument / result / scratch register 1

Table 9.2: Core Registers and AAPCS Usage

Registers R0-R3 are used to pass parameters to a function and they are not preserved. The compiler does not generate assembler code to preserve the values of these registers. R0 is also used for return value of a function.

Registers R4-R11 are preserved by the called function. If the compiler generated assembler code uses registers in R4-R11, then the compiler generate assembler code to automatically push/pop the used registers in R4-R11 upon entering and exiting the function.

R12-R15 are special purpose registers. A function that has the `__svc_indirect` keyword makes the compiler put the first parameter in the function to R12 followed by an `SVC` instruction. R13 is the stack pointer (SP). R14 is the link register (LR), which normally is used to save the return address of a function. R15 is the program counter (PC).

Note that the exception stack frame automatically backs up R0-R3, R12, LR and PC together with the xPSR. This allows the possibility of writing the exception handler in purely C language without the need of having a small piece of assembly code to save/restore R0-R3, LR and PC upon entering/exiting an exception handler routine.

9.3 Cortex Microcontroller Software Interface Standard (CMSIS)

The Cortex Microcontroller Software Interface Standard (CMSIS) was developed by ARM. It provides a standardized access interface for embedded software products (see Figure 9.1). This improves software portability and re-usability. It enables software solution suppliers to develop products that can work seamlessly with device libraries from various silicon vendors [2].

Figure 9.1: Role of CMSIS[5]

The CMSIS uses standardized methods to organize header files that makes it easy to learn new Cortex-M microcontroller products and improve software portability. With the `<device>.h` (e.g. `LPC17xx.h`) and system startup code files (e.g., `startup_LPC17xx.s`), your program has a common way to access

- **Cortex-M processor core registers** with standardized definitions for NVIC, SysTick, MPU registers, System Control Block registers, and their core access functions (see `core_cm*.ch` files).
- **system exceptions** with standardized exception number and handler names to allow RTOS and middleware components to utilize system exceptions without having compatibility issues.
- **intrinsic functions with standardized name** to produce instructions that cannot be generated by IEC/ISO C.
- **system initialization** by common methods for each MCU. For example, the standardized `SystemInit()` function to configure clock.
- **system clock frequency** with standardized variable named as `SystemFrequency` defined in the device driver.

- **vendor peripherals** with standardized C structure.

Figure 9.2: CMSIS Organization[2]

9.3.1 CMSIS files

The CMSIS is divided into multiple layers (See Figure 9.2). For each device, the MCU vendor provides a device header file `<device>.h` (e.g., `LPC17xx.h`) which pulls in additional header files required by the device driver library and the Core Peripheral Access Layer (see Figure 9.3).

By including the `<device>.h` (e.g., `LPC17xx.h`) file into your code file. The first step to initialize the system can be done by calling the CMSIS function as shown in Listing 9.1.

```
SystemInit(); // Initialize the MCU clock
```

Listing 9.1: CMSIS SystemInit()

The CMSIS compliant device drivers also contain a startup code (e.g., `startup_LPC17xx.s`), which include the vector table with standardized exception handler names (See Section 9.3.3).

9.3.2 Cortex-M Core Peripherals

We only introduce the NVIC programming in this section. The Nested Vectored Interrupt Controller (NVIC) can be accessed by using CMSIS functions (see Figure 9.4). As an

Figure 9.3: CMSIS Organization[2]

	Function definition	Description
void	NVIC_SystemReset (void)	Resets the whole system including peripherals.
void	NVIC_SetPriorityGrouping (uint32_t priority_grouping)	Sets the priority grouping.
uint32_t	NVIC_GetPriorityGrouping (void)	Returns the value of the current priority grouping.
void	NVIC_EnableIRQ (IRQn_Type IRQn)	Enables the interrupt IRQn.
void	NVIC_DisableIRQ (IRQn_Type IRQn)	Disables the interrupt IRQn.
void	NVIC_SetPriority (IRQn_Type IRQn, int32_t priority)	Sets the priority for the interrupt IRQn.
uint32_t	NVIC_GetPriority (IRQn_Type IRQn)	Returns the priority for the specified interrupt.
void	NVIC_SetPendingIRQ (IRQn_Type IRQn)	Sets the interrupt IRQn pending.
IRQn_Type	NVIC_GetPendingIRQ (IRQn_Type IRQn)	Returns the pending status of the interrupt IRQn.
void	NVIC_ClearPendingIRQ (IRQn_Type IRQn)	Clears the pending status of the interrupt IRQn, if it is not already running or active.
IRQn_Type	NVIC_GetActive (IRQn_Type IRQn)	Returns the active status for the interrupt IRQn.

Figure 9.4: CMSIS NVIC Functions[2]

example, the following code enables the UART0 and TIMER0 interrupt

```

NVIC_EnableIRQ(UART0_IRQn); // UART0_IRQn is defined in LPC17xx.h
NVIC_EnableIRQ(TIMER0_IRQn); // TIMER0_IRQn is defined in LPC17xx.h

```

9.3.3 System Exceptions

Writing an exception handler becomes very easy. One just defines a function that takes no input parameter and returns void. The function takes the name of the standardized exception handler name as defined in the startup code (e.g., `startup_LPC17xx.s`). The following listing shows an example to write the UART0 interrupt handler entirely in C.

```
void UART0_Handler (void)
{
    // write your IRQ here
}
```

Another way is to use the embedded assembly code:

```
__asm void UART0_Handler(void)
{
    ; do some asm instructions here
    BL __cpp(a_c_function) ; a_c_function is a regular C function
    ; do some asm instructions here,
}
```

9.3.4 Intrinsic Functions

ANSI cannot directly access some Cortex-M3 instructions. The CMSIS provides intrinsic functions that can generate these instructions. The CMSIS also provides a number of functions for accessing the special registers using `MRS` and `MSR` instructions. The intrinsic functions are provided by the RealView Compiler. Table 9.3 lists some intrinsic functions that your RTOS project most likely will need to use. We refer the reader to Tables 613 and 614 one page 650 in Section 34.2.2 of [4] for the complete list of intrinsic functions.

9.3.5 Vendor Peripherals

All vendor peripherals are organized as C structure in the `<device>.h` file (e.g., `LPC17xx.h`). For example, to read a character received in the RBR of UART0, we can use the following code.

```
unsigned char ch;
ch = LPC_UART0->RBR; // read UART0 RBR and save it in ch
```

Instruction		CMSIS Intrinsic Function
CPSIE I		<code>void __enable_irq(void)</code>
CPSID I		<code>void __disable_irq(void)</code>
Special Register	Access	CMSIS Function
CONTROL	Read	<code>uint32_t __get_CONTROL(void)</code>
	Write	<code>void __set_CONTROL(uint32_t value)</code>
MSP	Read	<code>uint32_t __get_MSP(void)</code>
	Write	<code>void __set_MSP(uint32_t value)</code>
PSP	Read	<code>uint32_t __get_PSP(void)</code>
	Write	<code>void __set_PSP(uint32_t value)</code>

Table 9.3: CMSIS intrinsic functions defined in `core_cmFunc.h`

9.4 Accessing C Symbols from Assembly

Only embedded assembly is support in Cortex-M3. To write an embedded assembly function, you need to use the `__asm` keyword. For example the the function “`embedded_asm_function`” in Listing 9.2 is an embedded assembly function. You can only put assembly instructions inside this function. Note that inline assembly is not supported in Cortex-M3.

The `__cpp` keyword allows one to access C compile-time constant expressions, including the addresses of data or functions with external linkage, from the assembly code. The expression inside the `__cpp` can be one of the followings:

- A global variable defined in C

```
#define U32 unsigned int

typedef struct pcb {
    struct pcb *mp_next;
    U32 *mp_sp; //4 bytes offset from
               //the starting address of the structure
    //other variables...
} PCB;

#define SP_OFFSET 4

PCB g_pcb;
U32 g_var;
```

```

__asm embedded_asm_function(void) {
    LDR R3, __cpp(&g_pcb) ; load R3 with the address of g_pcb
    LDM R3, {R1, R2}      ; load R1 with g_pcb.mp_next
                          ; load R2 with g_pcb.mp_sp
    LDR R4, __cpp(g_var)  ; load R4 with the value of g_var
    STR R4, [R3, #SP_OFFSET] ; write R4 value to g_pcb.mp_sp
}

```

Listing 9.2: Example of accessing global variable from assembly

- A C function

```

extern void a_c_function(void);
...
__asm embedded_asm_function(void) {
    ;.....
    BL __cpp(a_c_function) ; a_c_function is regular C function
    ;.....
}

```

- A constant expression in the range of 0 – 255 defined in C.

```

unsigned char const g_flag;

__asm embedded_asm_function(void) {
    ;.....
    MOV R4, #__cpp(g_flag) ; load g_flag value to R4
    ;.....
}

```

Note the MOV instruction only applies to immediate constant value in the range of 0 – 255.

You can also use the IMPORT directive to import a C symbol in the embedded assembly function and then start to use the imported symbol just as a regular assembly symbol. For example

```

void a_c_function (void) {
    // do something
}

```

```

__asm embedded_asm_add(void) {
    IMPORT a_c_function ; a_c_function is a regular C function
    BL a_c_function    ; branch with link to a_c_function
}

```

Names in the `__cpp` expression are looked up in the C context of the `__asm` function. Any names in the result of the `__cpp` expression are mangled as required and automatically have `IMPORT` statements generated from them.

9.5 SVC Programming: Writing an RTX API Function

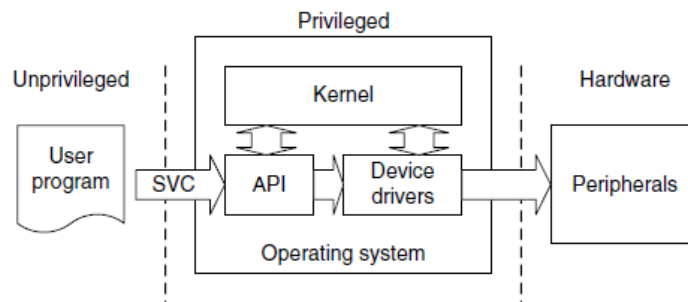

Figure 9.5: SVC as a Gateway for OS Functions [5]

A function in RTX API requires a service from the operating system. It needs to be implemented through the proper gateway by *trapping* from the user level into the kernel level. On Cortex-M3, the `SVC` instruction is used to achieve this purpose.

The basic idea is that when a function in RTX API is called from the user level, this function will trigger an `SVC` instruction. The `SVC_Handler`, which is the CMSIS standardized exception handler for `SVC` exception will then invoke the a kernel function that provides the actual service (see Figure 9.5). Effectively, the RTX API function is a wrapper that invokes `SVC` exception handler and passes corresponding kernel service operation information to the `SVC` handler.

To generate an `SVC` instruction, there are two methods. One is a direct method and the other one is an indirect method.

The direct method is to program at assembly instruction level. We can use the embedded assembly mechanism and write SVC assembly instruction inside the embedded assembly function. An example implementation of `int release_memory_block(void *memory_block)` is shown in Listing 9.3.

```
__asm int release_memory_block(void *memory_block) {
    LDR R12,=__cpp(k_release_memory_block)
    ; privileged mode code handling omitted
    SVC 0
    BX LR
    ALIGN
}
```

Listing 9.3: Code Snippet of `release_memory_block`

The corresponding kernel function is the C function `k_release_memory_block`. This function entry point is loaded to `r12`. Then `SVC 0` causes an SVC exception with immediate number 0. In the SVC exception handler, we can then branch with link and exchange to the address stored in `r12`. Listing 9.4 is an excerpt of the `SVC_handler` in `HAL.c` from the starter code (https://github.com/yqh/SE350/blob/master/manual_code/SVC/src/HAL.c).

```
__asm void SVC_Handler(void) {
    MRS R0, PSP

    ;Extract SVC number, if SVC 0, then do the following

    LDM R0, {R0-R3, R12}; Read R0-R3, R12 from stack
    ; code to save cpu registers omitted

    BLX R12 ; R12 contains the kernel function entry point

    ;Code to restore registers omitted

    MVN LR, #:NOT:0xFFFFFFFF; set EXC_RETURN, thread mode, PSP
    BX LR
}
```

Listing 9.4: Code Snippet of `SVC_Handler`

The indirect method is to ask the compiler to generate the SVC instruction from C code. The ARM compiler provides an intrinsic keyword named `__svc_indirect` which passes an operation code to the SVC handler in `r12[3]`. This keyword is a function qualifier. The two inputs we need to provide to the compiler are

- `svc_num`, the immediate value used in the SVC instruction and
 - `op_num`, the value passed in `r12` to the handler to determine the function to perform.
- The following is the syntax of an indirect SVC.

```
__svc_indirect(int svc_num)
    return_type function_name(int op_num[, argument-list]);
```

The system handler must make use of the `r12` value to select the required operation. For example, the `release_memory_block` is a user function with the following signature:

```
#include <rtx.h>
int release_memory_block(void *memory_block);
```

In `rtx.h`, the following code is relevant to the implementation of the function.

```
#define __SVC_0 __svc_indirect(0)
extern int k_release_memory_block(void *);
#define release_memory_block(p_mem_blk) _release_memory_block((U32)
    k_release_memory_block, p_mem_blk)
extern int _release_memory_block(U32 p_func, void *p_mem_blk) __SVC_0;
```

The compiler generates two assembly instructions

```
LDR.W r12, [pc, #offset]; Load k_release_memory_block in r12
SVC 0x00
```

The `SVC_handler` in Listing 9.4 then can be used to handle the SVC 0 exception.

9.6 UART Programming

To program a UART on MCB1700 board, one first needs to configure the UART by following the steps listed in Section 15.1 in [4] (referred as LPC17xx_UM in the sample code comments). Listings 9.5, 9.6 and 9.7 give one sample implementation of programming UART0 interrupts.

```

Listing 9.9: UART0 IRQ Sample Code uart_polling.c

9.7 Timer Programming

To program a TIMER on MCB1700 board, one first needs to configure the TIMER by following the steps listed in Section 21.1 in [4]. Listings 9.10 and 9.11 give one sample implementation of programming TIMER0 interrupts. The timer interrupt fires every one millisecond.

```

/**
 * @brief timer.h - Timer header file
 * @author Y. Huang
 * @date 2013/02/12
 */
#ifndef _TIMER_H_
#define _TIMER_H_

extern uint32_t timer_init ( uint8_t n_timer ); /* initialize timer
    n_timer */

```

```
#endif /* ! _TIMER_H_ */
```

Listing 9.10: Timer0 IRQ Sample Code timer.h

```
/**
 * @brief timer.c - Timer example code. Timer IRQ is invoked every 1ms
 * @author T. Reidemeister
 * @author Y. Huang
 * @author NXP Semiconductors
 * @date 2012/02/12
 */

#include <LPC17xx.h>
#include "timer.h"

#define BIT(X) (1<<X)

volatile uint32_t g_timer_count = 0; // increment every 1 ms

/**
 * @brief: initialize timer. Only timer 0 is supported
 */
uint32_t timer_init(uint8_t n_timer)
{
    LPC_TIM_TypeDef *pTimer;
    if (n_timer == 0) {
        /*
         Steps 1 & 2: system control configuration.
         Under CMSIS, system_LPC17xx.c does these two steps

         -----

         Step 1: Power control configuration.
                 See table 46 pg63 in LPC17xx_UM

         -----

         Enable UART0 power, this is the default setting
         done in system_LPC17xx.c under CMSIS.
         Enclose the code for your reference
         //LPC_SC->PCONP |= BIT(1);

         -----

         Step2: Select the clock source,
```

```

        default PCLK=CCLK/4 , where CCLK = 100MHZ.
        See tables 40 & 42 on pg56-57 in LPC17xx_UM.
-----

Check the PLL0 configuration to see how XTAL=12.0MHZ
gets to CCLK=100MHZ in system_LPC17xx.c file.
PCLK = CCLK/4, default setting in system_LPC17xx.c.
Enclose the code for your reference
//LPC_SC->PCLKSELO &= ~(BIT(3)|BIT(2));

-----

Step 3: Pin Ctrl Block configuration.
        Optional, not used in this example
        See Table 82 on pg110 in LPC17xx_UM
-----

*/
pTimer = (LPC_TIM_TypeDef *) LPC_TIM0;

} else { /* other timer not supported yet */
    return 1;
}

/*
-----

Step 4: Interrupts configuration
-----

*/

/* Step 4.1: Prescale Register PR setting
    CCLK = 100 MHZ, PCLK = CCLK/4 = 25 MHZ
    2*(12499 + 1)*(1/25) * 10^(-6) s = 10^(-3) s = 1 ms
    TC (Timer Counter) toggles b/w 0 and 1 every 12500 PCLKs
    see MR setting below
*/

Appendix A

MDK-ARM Installation

There is only a windows port for the Keil MDK-ARM for now. The MDK-ARM V4.60.0.0 direct download link is inside the Learn (<http://learn.uwaterloo.ca>)¹.

During the process of the installation of the MDK-ARM, you will be asked to add example code. Choose Keil(NXP) MCB1xxx Boards example projects (see Figure A.1).

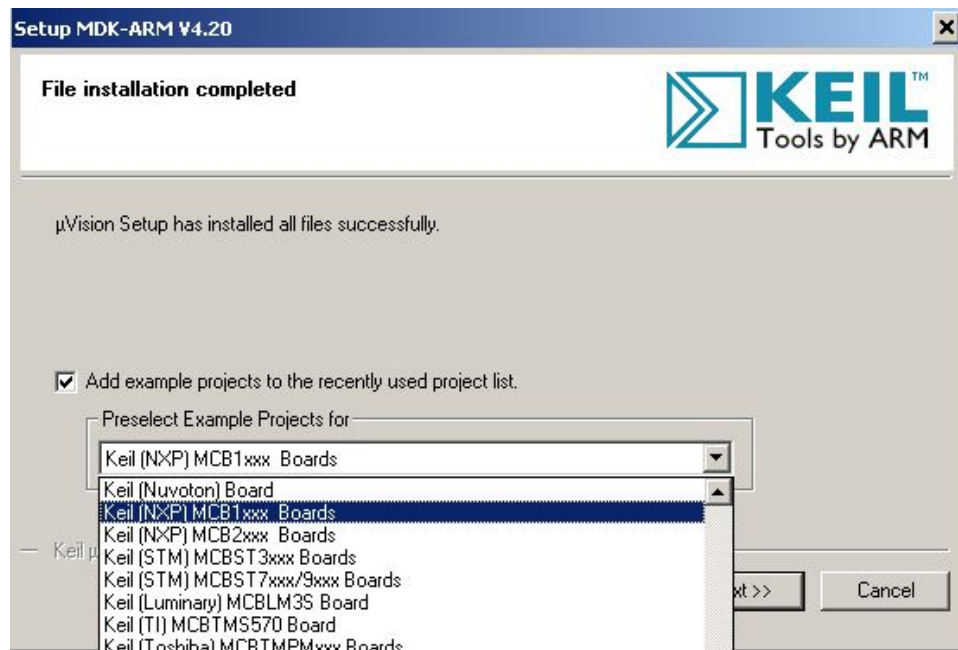

Figure A.1: MDK-ARM Installation Steps: Choose Example Projects

¹The latest version of MDK-ARM is at Keil website <http://www.keil.com/download/product/>. However the lab manual is written for V4.60.0.0. We haven't tested the latest version.

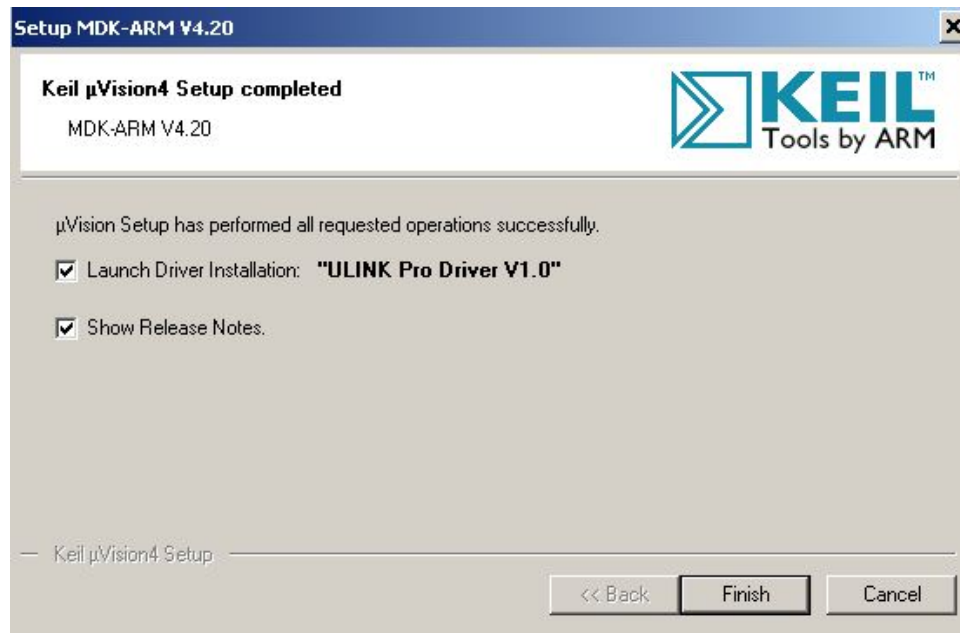

Figure A.2: MDK-ARM Installation Steps: Finish

At the last step of MDK-ARM installation, be sure that the launch the “ULINK Pro Driver

Figure A.3: MDK-ARM Installation Steps: ULINK Pro Driver

V1.0” driver installation check box is checked (see Figure A.2. Once you click “Finish” button, the ULINK Pro Driver installation starts. Click “Install” button to install the driver (see Figure A.3).

Appendix B

Forms

Lab administration related forms are given in this appendix.
